

SUMMARY

This project is an SQL-based Amazon E-commerce Database Management System developed using MySQL. The project focuses on designing and managing relational database tables for customers, products, orders, suppliers, reviews, and categories. It includes database creation, table modifications, and implementation of primary key and foreign key relationships to maintain data integrity.

The project demonstrates important SQL operations such as INSERT, UPDATE, DELETE, ALTER, JOIN, GROUP BY, HAVING, and ORDER BY. Various constraints like PRIMARY KEY, FOREIGN KEY, CHECK, UNIQUE, and DEFAULT are applied to ensure accurate and reliable data management within the database system.

Several business-oriented analytical queries were performed to generate insights from the e-commerce data. These include customer spending analysis, top-selling products, supplier stock tracking, product category analysis, order revenue calculation, and customer review evaluation. The project helps in understanding how SQL is used for real-world business reporting and decision-making.

Overall, this project enhanced my practical knowledge of relational database design, SQL query writing, data analysis, and database management concepts through a real-time Amazon-style business scenario.
